12 av disse er økonomisk viktige arter som utgjør ca. 2/3 av Nordsjøens fangstvolum

Økosystemstrukturen i Nordsjøen

NORTHERN Sub region:
 Deepest part of the shelf.
 Atlantic inflow

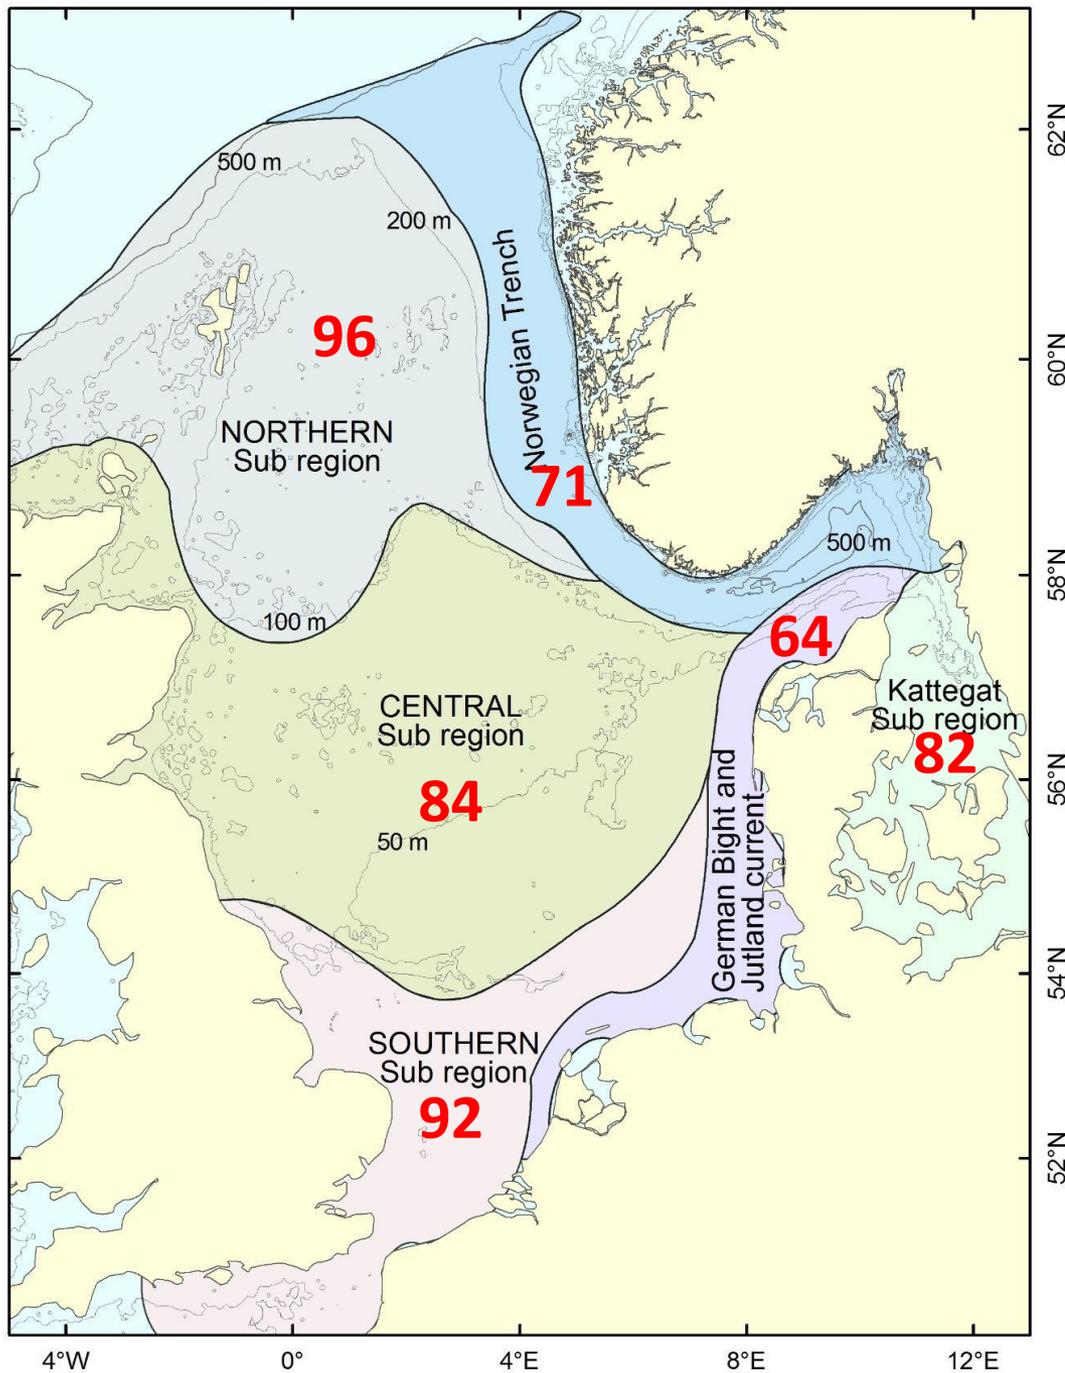

Norwegian Trench:
 Deepest region.
 Atlantic inflow and outflow of
 Coastal water

CENTRAL Sub region:
 Less influenced by both Atlantic
 and coastal waters

German Bight and Jutland C:
 Shallow and strongly influenced
 by fresh water runoff.

Kattegat Sub region:
 Shallow and strongly influenced
 Baltic water outflow

SOUTHERN Sub region:
 Shallow and strongly influenced
 by tidal mixing

**141 ARTER I HELE
NORDSJØEN**

31 fiskearter finnes bare i 2 økosystem underområder

Virkningene av klimaendringer i Nordsjøen

Climate Change and Distribution Shifts in Marine Fishes

Allison L. Perry,^{1*} Paula J. Low,^{2†} Jim

We show that the distributions of both exploited fish species have responded markedly to recent climate change, with nearly two-thirds of species shifting in mean latitude. For species with northerly or southerly distributions, half have shown boundary shifts with warming. Species with shifting distributions have smaller body sizes than nonshifting species. Further, there are profound impacts on commercial fisheries through changes in community interactions and alterations in community interactions.

Har fiskeartene generelt sett forflyttet seg nordover i Nordsjøen?

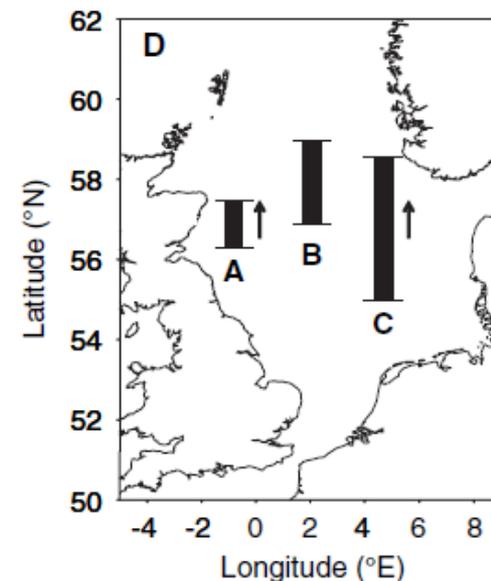

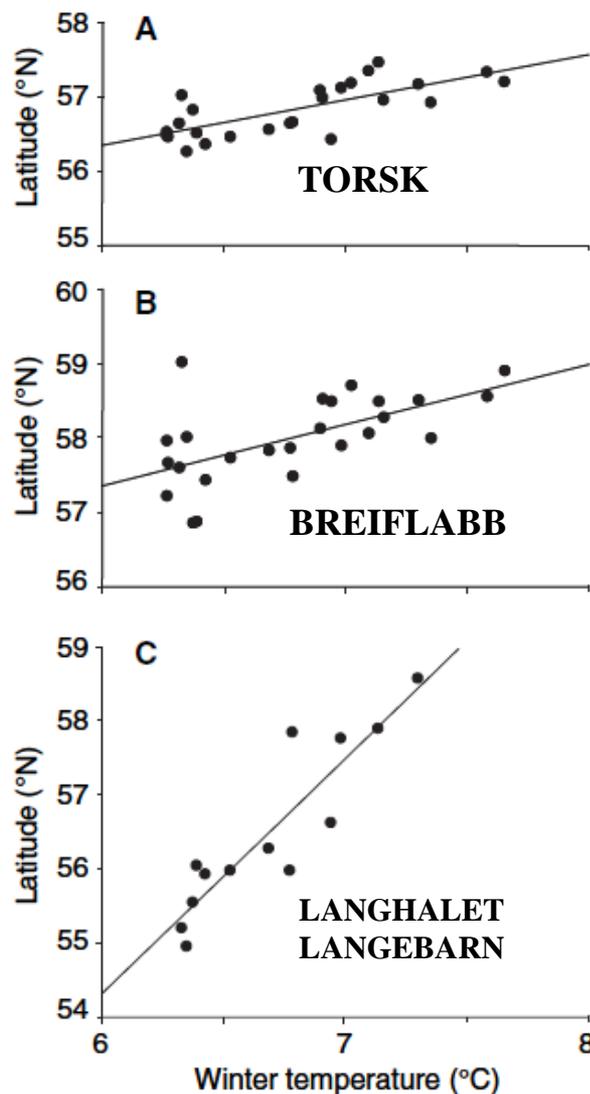

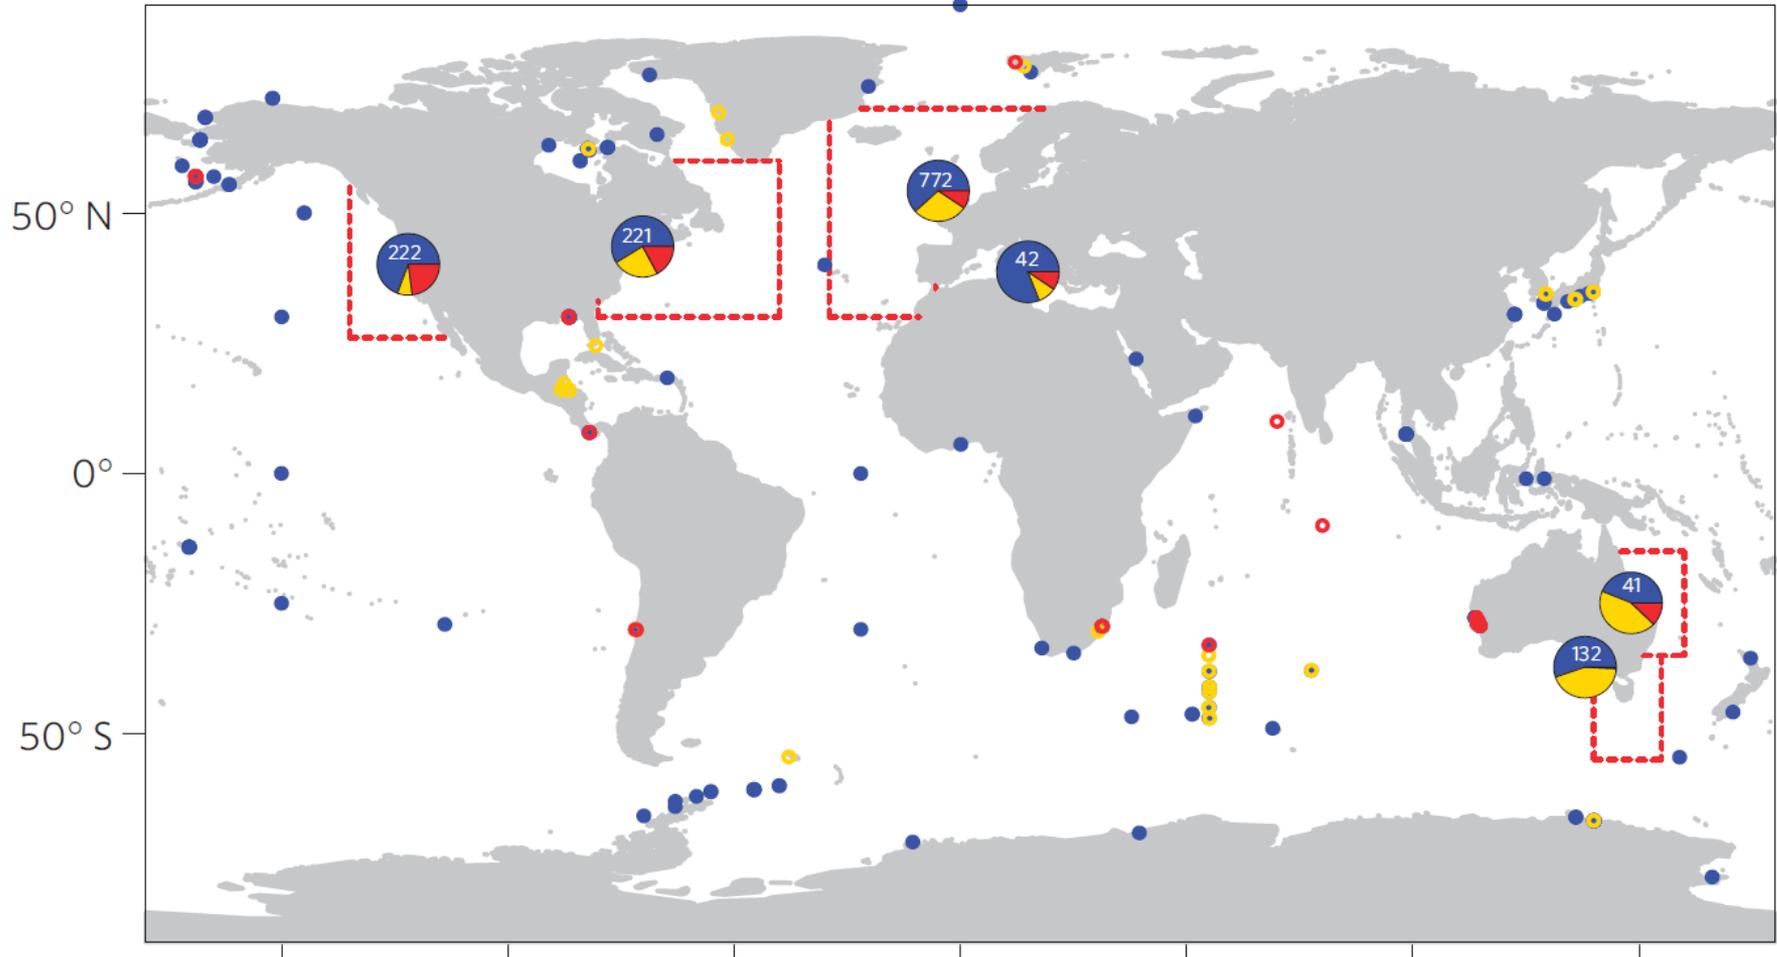

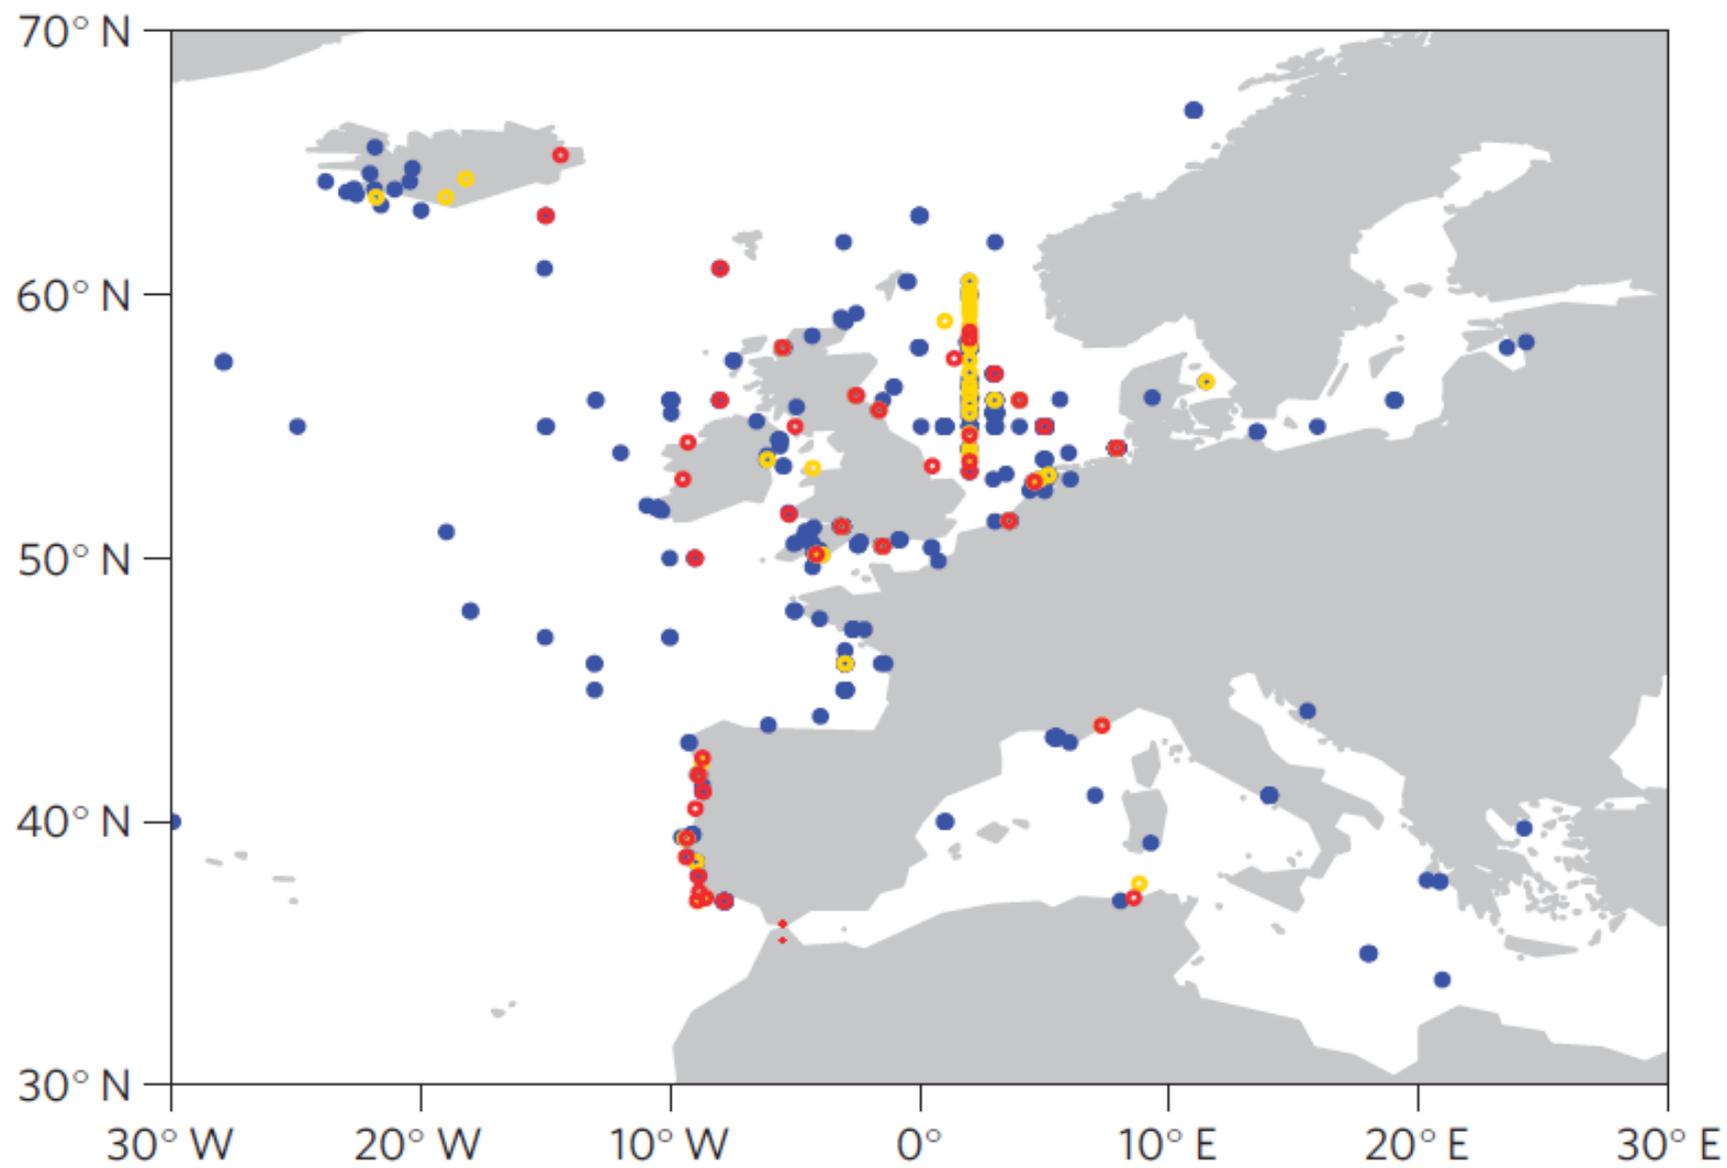

Fig. 1. Examples of North Sea fish distributions that have shifted north with climatic warming. Relationships between mean latitude and 5-year running mean winter bottom temperature for (A) cod, (B) anglerfish, and (C) snake blenny are shown. In (D), ranges of shifts in mean latitude are shown for (A), (B), and (C) within the North Sea. Bars on the map illustrate only shift ranges of mean latitudes, not longitudes. Arrows indicate where shifts have been significant over time, with the direction of movement. Regression details are in Table 1.

Climate Change and Distribution Shifts in Marine Fishes

Allison L. Perry,^{1*} Paula J. Low,^{2†} Jim

We show that the distributions of both exploited marine fishes have responded markedly to recent climate change, with nearly two-thirds of species shifting in mean latitude in the last 50 years. For species with northerly or southerly distributions, half have shown boundary shifts with warming. Species with shifting distributions have smaller body sizes than nonshifting species. Further, there are profound impacts on commercial fisheries through changes in distribution and alterations in community interactions.

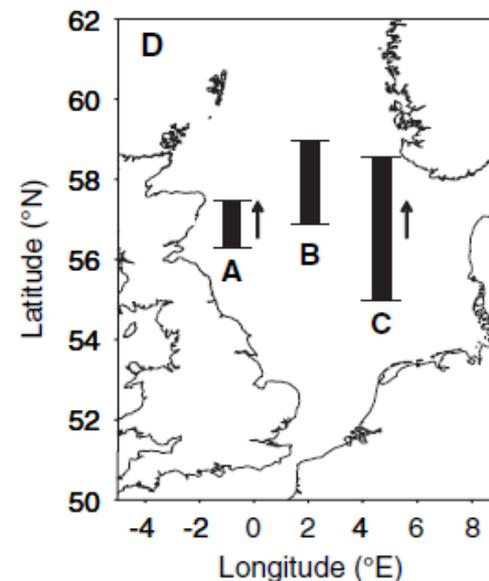

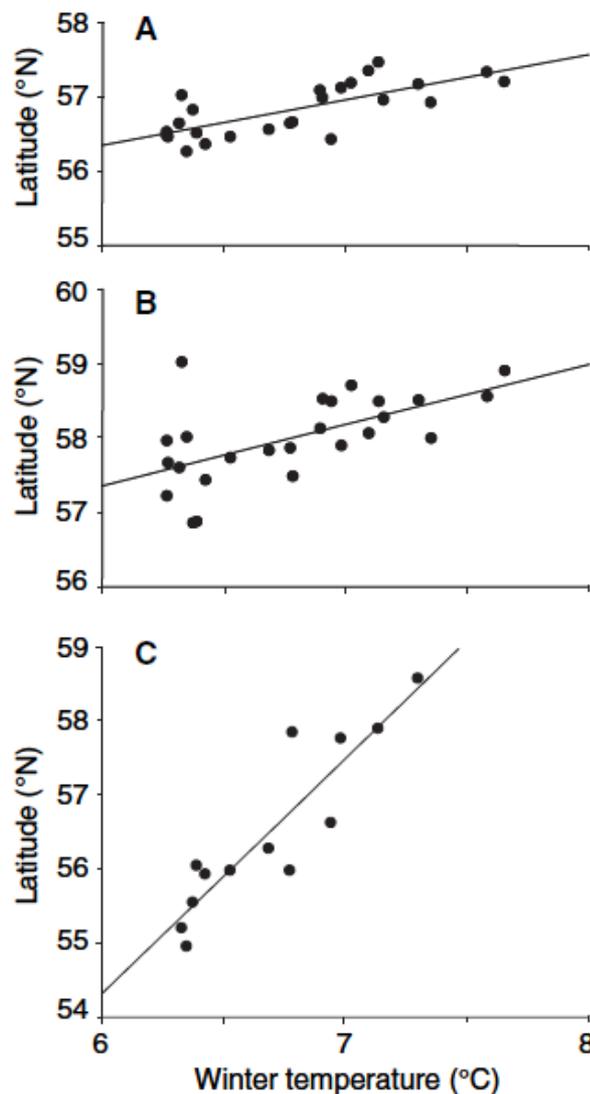

Fig. 1. Examples of North Sea fish distributions that have shifted north with climatic warming. Relationships between mean latitude and 5-year running mean winter bottom temperature for (A) cod, (B) anglerfish, and (C) snake blenny are shown. In (D), ranges of shifts in mean latitude are shown for (A), (B), and (C) within the North Sea. Bars on the map illustrate only shift ranges of mean latitudes, not longitudes. Arrows indicate where shifts have been significant over time, with the direction of movement. Regression details are in Table 1.
